ABSTRACT

Light Detection and Ranging (LIDAR) data compression has been an active research field for last few years because of its large storage size. When LIDAR has large number of data points, the surface generation represented by interpolation methods may be inefficient in both storage and computational requirements. This paper presents a newly developed compression scheme for the LIDAR data based on second generation wavelet. A new interpolation wavelet filter has been applied in two steps, namely splitting and elevation. In the splitting step, a triangle has been divided into several sub-triangles and the elevation step has been used to 'modify' the point values (point coordinates for geometry) after the splitting. Then, this data set is compressed at the desired locations by using second generation wavelets. The quality of geographical surface representation after using proposed technique is compared with the original LIDAR data. The results show that this method can be used for significant reduction of data set.

KEYWORDS: Light Detection and Ranging (LIDAR), Delaunay triangulation, Triangulated irregular network (TIN), Geographical information system, Lifting scheme, Second generation wavelet

1. INTRODUCTION

Recently, most of the methods for image compression are based on wavelets and related techniques. Wavelet approaches for image compression tend to outperform Fourier approaches because of its ability to represent both spatially localized features and smooth regions in an image. The superior compression capability of wavelets combined with their natural multiresolution structure makes them a good representation for storing images. While working with dyadic wavelet decomposition digital images are represented by wavelet coefficients. These types of representation in dyadic wavelet decomposition are known as linear decomposition over a fixed orthogonal basis. The non-linearity in the approximation of images by wavelets is introduced by the thresholding of the wavelet coefficients. This type of approximation can be viewed as *mildly* nonlinear. Recently, several *highly* nonlinear methods for capturing the geometry of images were developed, such as wedgelets [1]; as well as edge-adapted nonlinear multiresolution and geometric spline approximation [2].

This paper presents a new approach for LIDAR data compression method using second generation wavelets. A random set of points has been approximated to represent a

surface by Delaunay triangulation. The theory, computations, and applications of Delaunay triangulations and Voronoi diagrams have been described in details in the literature [2-8]. The present work describes a fast algorithm based on Tsai's Convex Hull Insertion algorithm [7-8], for the construction of Delaunay triangulations of arbitrary collections of points on the Euclidean plane. The original algorithm has been improved further for a faster computation of geometric structures. The source code has been written in FORTRAN compiler. Once the triangulated irregular network has been created from the random set of points, it was further subjected to compression by using second generation wavelets. Results were shown in a comparative study basis for the TIN data compression at different level of resolution.

2. DELAUNAY TRIANGULATION

Many researchers [3, 9-10] have suggested different ways to construct triangulations with the local equilateral property. A well known construction called the Delaunay Triangulation simultaneously optimizes several of the quality measures such as max-min angle, min-max circumcircle, and min-max min-containment circle. The Delaunay triangulation "DT" of a point set is the planar dual of the famous Voronoi diagram. The Voronoi diagram is a partition of the plane into polygonal cells, one for each input point so that the cell for input point 'a' consists of the region of the plane closer to 'a' than to any other input point. So long as no four points lie on a common circle then each vertex of the Voronoi diagram has degree three and the DT which has a bounded face for each Voronoi vertex and vice versa will indeed be a triangulation. If four or more points do lie on a common circle then these points will be the vertices of a larger face that may then be triangulated to give a triangulation containing the DT. Voronoi diagrams and Delaunay triangulations have been generalized in numerous directions. For more information on Delaunay triangulations and Voronoi diagrams see the surveys by Fortune and Aurenhammer [11]. There is a nice relationship between Delaunay triangulation and three dimensional convex hulls. Lift each point of the input to a paraboloid in three-space by mapping the point with coordinates (x, y) to the point $(x, y, x^2 + y^2)$. The convex hull of the lifted points can be divided into lower and upper parts: a face belongs to the lower convex hull if it is supported by a plane that separates the point set from $(0, 0, -\infty)$. It can be shown that the DT of the input points is the projection of the lower convex hull onto the xy -plane as depicted in Figure 1. Finally a direct characterization: if a and b are input points the DT contains the edge $\{a, b\}$ if and only if there is a circle through a and b that intersects no other input points and contains no input points in its interior. Moreover each circumscribing circle (circumcircle) of a DT triangle contains no input points in its interior.

Some properties of Delaunay triangulations have been discussed as follows:

Let Y denotes a finite planar point set.

- A Delaunay triangulations $D(Y)$ of Y is one, such that for any triangle in $D(Y)$, the interior of its circumcircle does not contain any point from Y . This specific property is termed as Delaunay property.
- The Delaunay triangulation $D(Y)$ of Y is unique, provided that no four points in Y are co-circular. Since neither the set X of pixels nor its subsets satisfy this condition, we initially perturb the pixel positions in order to guarantee unicity of the Delaunay triangulations of X and of its subsets. Each perturbed pixel corresponds to one unique unperturbed pixel. From now on, we denote the set of perturbed pixels by X , and the set of unperturbed pixels by \tilde{X} .

Figure 1 The lifting transformation maps the DT to the lower convex hull

- For any $y \in Y$, $D(Y \setminus y)$ can be computed from $D(Y)$ by a *local* update. This follows from the Delaunay property, which implies that only the cell $C(y)$ of y in $D(Y)$ needs to be retriangulated. Recall that the cell $C(y)$ of y is the domain consisting of all triangles in $D(Y)$ which contain y as a vertex. Figure 1 shows a vertex $y \in D(Y)$ and the Delaunay triangulation of its cell $C(y)$.
- $D(Y)$ provides a partitioning of the convex hull $[Y]$ of Y .

3. INTERPOLATION WAVELET FILTERS FOR TIN

An interpolation wavelet filter for TIN lies in subdivision process which has two steps [12]. One is a splitting step; the other one is an elevation step. In the splitting step, a triangle is divided into several sub-triangles. The elevation step is to calculate the point values (point coordinates for geometry) after the splitting. Let us discuss this partition step mathematically.

Consider a data set to be partitioned into two groups, called s and e . Using P to express the point coordinates, one can construct an estimation of P_s based on P_e .

$$\tilde{P}_s = E(P_e) \quad (1)$$

The estimation function (filter) E can be a local estimation or global estimation. A global estimation is generally computationally expensive; therefore, a local estimation using only neighboring points is preferred. After the estimation step, a wavelet term, W_s and an approximation term, A_s for the original data can be constructed as:

$$\begin{aligned} W_s &= P_s - \tilde{P}_s \\ A_e &= P_e + C(W_s) \end{aligned} \quad (2)$$

The correction function C is a customizable function based on different optimization requirements. An inverse transform can be constructed as:

$$\begin{aligned} P_e &= A_e - C(W_s) \\ P_s &= W_s + E(P_e) \end{aligned} \quad (3)$$

If the original point set can be partitioned into a nested group, then the above process can be iteratively applied to different sets in this group. A nested group has the flowing structure:

$$\begin{aligned} e^0 \subset e^1 \subset e^2 \subset \dots \subset e^N \\ e^i \cup s^i = e^{i+1}, i = 0, \dots, N-1 \end{aligned} \quad (4)$$

e^N denotes the finest representation of the geometry. e^N can be partitioned into e^{N-1} and s^{N-1} ; then e^{N-1} can be partitioned into e^{N-2} and s^{N-2} , and so on, until e^1 is partitioned into e^0 and s^0 . Note that the superscripts are used to represent different resolutions (larger numbers represent finer resolution). Based on this nested (or hierarchical) structure of the partition, one can construct wavelets and approximations of the data as:

$$\begin{aligned} A_{e^N} &= P_{e^N} \\ \left\{ \begin{aligned} e^i &= e^{i-1} \cup s^{i-1}, B_{e^{i-1}} = A_{e^{i-1}}(e^{i-1}), B_{s^{i-1}} = A_{e^{i-1}}(s^{i-1}) \\ W_{e^{i-1}} &= B_{e^{i-1}} - E(B_{e^{i-1}}), i = N, N-1, \dots, 1 \\ A_{e^{i-1}} &= B_{e^{i-1}} + C(W_{s^{i-1}}) \end{aligned} \right. \quad (5) \end{aligned}$$

Here, B is an intermediate symbol to represent the partitioning result. A_{e^i} is partitioned into two components: $A_{e^i}(e^{i-1})$ and $A_{e^i}(s^{i-1})$, which belong to e^{i-1} and s^{i-1} respectively. Based on equation (5), the original data P_{e^N} is decomposed into A_{e^0} , W_{s^0} , W_{s^1} , \dots , $W_{s^{N-1}}$. Equation (5) is the analysis transform, which decomposes the finer representation into a coarser representation plus details. The synthesis transforms in the inverse transform and is shown in equation (6). The reconstructed A_{e^0} , A_{e^1} , \dots , $A_{e^N} (= P_{e^N})$ yield a multiresolution representation of the original data.

$$\begin{cases} B_{e^i} = A_{e^i} - C(W_{s^i}) \\ B_{s^i} = W_{s^i} + E(B_{e^i}), i = 0, 1, \dots, N-1 \\ e^{i+1} = e^i \cup s^i, A_{e^{i+1}}(e^i) = B_{e^i}, A_{e^{i+1}}(s^i) = B_{s^i} \end{cases} \quad (6)$$

$$P_{e^N} = A_{e^N}$$

In the above derivation of a wavelet representation [13-18], the process does not depend on a regular setting for the data; therefore, it can be used in both the regular and irregular setting cases. This is an important advantage of the lifting scheme [17-18]. If the filters E and C are the same for every point at a given level, the scheme is a uniform scheme. If they also do not change with the resolution, i , the scheme is a stationary scheme as well. However, equations (5) and (6) are general formulas. Non-stationary and non-uniform schemes can be written in this form with indices on E and C . Nevertheless, those schemes could cost more computing resources and may be less effective for data compression in GIS applications.

3.1 AN EXAMPLE

Figure 4 An example that illustrates the basic idea of the wavelet filter construction process

Figure 4 shows an example that illustrates the basic idea of the above construction process. Here E and C depend on e^0 and s^0 , therefore, it is a non-stationary and non-uniform transform. Given irregular data on points $e^1 = \{t_0, t_1, t_2, t_3, t_4\}$, the one step partition and wavelet transform are:

$$\begin{aligned} A_{e^1} &= P_{e^1}, e^0 = \{t_0, t_2, t_4\}, s^0 = \{t_1, t_3\} \\ e^1 &= e^0 \cup s^0, B_{e^0} = A_{e^1}(e^0), B_{s^0} = A_{e^1}(s^0), \lambda_1 = \frac{t_1 - t_0}{t_2 - t_0}, \lambda_2 = \frac{t_3 - t_2}{t_4 - t_2} \\ W_{s^0} &= B_{s^0} - (B_{e^0}) = \begin{bmatrix} P_{t_1} \\ P_{t_3} \end{bmatrix} - \begin{bmatrix} 1 - \lambda_1 & \lambda_1 & 0 \\ 0 & 1 - \lambda_2 & \lambda_2 \end{bmatrix} \begin{bmatrix} P_{t_0} \\ P_{t_2} \\ P_{t_4} \end{bmatrix} \\ A_{e^0} &= B_{e^0} + C(W_{s^0}) = \begin{bmatrix} P_{t_0} \\ P_{t_2} \\ P_{t_4} \end{bmatrix} + \begin{bmatrix} 1 - \lambda_1 & 0 \\ \lambda_1 & 1 - \lambda_2 \\ 0 & \lambda_2 \end{bmatrix} \begin{bmatrix} W_{t_1} \\ W_{t_3} \end{bmatrix} \end{aligned} \quad (7)$$

In this example, a linear estimator and corrector are used for E and C . If λ_1 and λ_2 are 0.5, the correction step makes the norm defined in equation (8) take a similar value than the uncorrected value. (Note that in equation (8), $A_{e^0}(t_j)$ for $t_j \in e^0$ refers to the estimation value $E(A_{e^0})$ at t_j . This is an example of the optimization in the correction step. Equation (7) is the analysis transform for the first step. The synthesis transform can be derived by replacing the estimator and the corrector in equation (6).

$$\text{norm} = \sum_{t_j \in e_1} (A_{e^1}(t_j) - A_{e^0}(t_j))^2 \quad (8)$$

4. PROPOSED ALGORITHM

The scheme described in previous section 3.1 is one type of filter based on the lifting scheme. This is called an approximation filter, in which every point value will change after each iteration. The other type of filter based on the lifting scheme is an interpolation filter, in which a point value reaches its final position once it is calculated. For GIS terrain data, however, interpolation is generally preferred because point values are often more useful than a general shape. Therefore, interpolation wavelet filters will be used in this research for processing three-dimensional terrain data.

First the approximation of the function was determined linearly. Then the lifting scheme was used to determine the best basis function and the coefficients. Normally, in practice the surface data consists of many frequency bands and transients. For limited samples, boundary filters are preferred over other techniques. The lifting scheme has been employed to provide the boundary high and low pass filters.

The generating process for the LIDAR data compression is as follows:

1. Due to randomly distributed raw data points, the data is interpolated by means of a linear function. It is aiming to enable processing with regularly distributed grid data.
2. Using the Delaunay algorithm the TIN model of the surface has been calculated. For each triangle in the TIN model the coordinates of the vertices and their respective height values of the three points that compose it were calculated.
3. The adjacency matrix that formed by the bounded edges for all triangles has been calculated.
4. The coordinates of the vertices and triangle edges have been rewritten in WTIN data structure.
5. The wavelet filter for each triangle has been calculated based on the area method as described in section 4.1. Wavelet coefficients have been determined to check and compare the area of each triangle based on lifting scheme (please see section 4.1). If the wavelet coefficient value is much higher than the threshold value then that vertices were retained. If the difference falls below a predefined threshold the original points are selected. This process is completed with the number points added during the presented iteration and was continued till all the points were checked.
6. By using iterative processing, the original LIDAR points were compared with the compressed data and their respective Peak Signal to Noise Ratio (PSNR) values were calculated for both images to compare the compression ratio.

4.1 CODING SCHEME

Figure 5 A surface showing the areas of the triangles to calculate the wavelet coefficients

The algorithm can be described as the Figure 5. The image to be encoded can be regarded as a discrete surface, i.e., a finite set of points in three-dimensional (3-D) space, by considering a non-negative discrete function of two variables $F(x, y)$ and establishing the correspondence between the image and the surface $A = \{(x, y, c) | c = F(x, y)\}$, so that each point in A corresponds to a pixel in the image; the couple (x, y) gives the pixel's position in the XY plane, while c is the point's height.

Our goal is to approximate A by a discrete surface $B = \{(x, y, d) | d = G(x, y)\}$, defined by means of a finite set of points. Let T be a generic triangle on the XY of vertices:

$$\left\{ \begin{array}{lll} P_1 = (x_1, y_1), & P_2 = (x_2, y_2), & P_3 = (x_3, y_3), \\ \text{And let} & & \\ c_1 = F(x_1, y_1), & c_2 = F(x_2, y_2), & c_3 = F(x_3, y_3), \end{array} \right. \quad (9)$$

Where P_1, P_2 and P_3 are represented as

$$(x_1, y_1, c_1), (x_2, y_2, c_2), (x_3, y_3, c_3) \in A.$$

Let O be the centroids of the triangle which means a new point after adding into the triangulation. Let A_1, A_2 and A_3 be the area of the three triangles. Then the total area A can be represented as:

$$A = A_1 + A_2 + A_3 \quad (10)$$

The detail coefficient can be represented as in equation 11.

$$d^n = Z^n - P(Z_e^n) \quad (11)$$

Where, d^n is the detail coefficient at the n^{th} level and $P(Z_e^n)$ is the predicted value at n^{th} level and Z^n is the values at the odd samples.

The equation above can be rewritten in a general form for $n-1^{\text{th}}$ level as

$$Z^{n-1} = Z_{\text{even}}^n + C(d^n) \quad (12)$$

where $C(d^n)$

$$\begin{cases} P = \begin{bmatrix} \frac{A_1}{A} & \frac{A_2}{A} & \frac{A_3}{A} \end{bmatrix} \\ C = P^T \end{cases} \quad (13)$$

Thus, by changing the correction factor C in equation 13, we can select the wavelet coefficients. These wavelet coefficients will determine the number of “significant points” that can be removed from the triangulation. These significant points will be used to represent the surface.

5. EXPERIMENTAL RESULTS

All algorithms were coded in Visual Fortran and MATLAB and executed on a Pentium IV, 256 MB RAM machine. The optimized code is about 2000 lines of Visual Fortran and 500 lines of MATLAB. To evaluate the performance of the wavelet based triangulation compression method several test data were used. The wavelet based triangulation compression method gives consistently better performance for the LIDAR data that we used. This section presents some results of the algorithm on LIDAR data using the wavelet based triangulation compression method at different levels of quality.

In our test, at each recursion step about 25% of the vertices are removed by using the second generation wavelet and lifting scheme. The number of triangles in the hierarchy is at most only three times larger than the number of triangles of the initial triangulation. We next examine the storage overhead caused by the maintenance of the hierarchy. The total amount of storage in bytes of the data structure described in previous section, which may include multiple copies of the same triangle, is only 4 to 5 times larger than the storage of the initial triangulation. In our implementation, this gave a total memory requirement for the hierarchical representation of a terrain of n data points of roughly $O(n \log n)$ bytes. The data structure of Delaunay triangulation is different from the data structure of in Wavelet compression in two ways. First, we no longer store multiple copies of the same triangle, instead we store for each triangle the level at which it was created. Second, we introduce the intermediate nodes, which reduce the total number of pointers in the structure. Together these two changes reduce the storage requirement by one third, which means that the storage is about 3.5 times as much as the storage for the initial terrain.

If the increase in storage would still be too much, it is possible to have a trade-off between the size of the structure and the difference between subsequent levels. In particular, instead of requiring the deleted vertices to form an independent set, we can require that they form independent groups of a certain size.

5.1 DATA USED

Two different sets of LIDAR data have been collected to check the efficiency of the compression program. The data were in ASCII format describing the x , y and z values for the points.

In the first step the TIN model for the surface using the Delaunay algorithm has been calculated. Figure 5 shows the LIDAR data represented in terms of TIN. It can be observed that most of the triangles generated by the program follow the Delaunay criterion. The above Figure shows the TIN model for 5000 points. On the top left portion of the Figure 6 shows

thin and flat triangles. This was due to the lack of intermediate points in between because of the valley.

Figure 6 The TIN model (Red colored lines are the edges of the triangles and blue points are the vertices that make the triangles.)

The original LIDAR data was in an irregular fashion. Delaunay triangulation method for the creation of the TIN has been applied to the original data. A new algorithm has been developed for the creation of the TIN. Furthermore, TIN was compressed using the second generation wavelets. A new algorithm for second generation wavelet compression is proposed. Based on the initial configuration of the original TIN, different resolutions are constructed during wavelet analysis. Figures 7a, 7b and 8a, 8b show the results computed using the wavelet based lifting scheme algorithm. Figure 7a shows the original data. Figure 8a shows the results after 12% compression and Figure 9a shows after 23% compression. Figure 9b shows the triangulation of the image after compression. Different compression schemes, such as Huffman coding can be applied to these wavelet coefficients to further reduce the storage size. This work also provides current implementation of wavelet coefficients during the compression operation. The proposed algorithm has the multiresolution capability and easy to compress due to large number of wavelet coefficients with small magnitudes which is suitable for distributed GIS applications such as web displaying.

6. CONCLUSION

The construction of Triangulated Irregular Network using Delaunay triangulation for the LIDAR data has been shown. This approach uses fast and efficient second generation wavelets algorithm for multiresolution analysis of GIS data compression. This algorithm is easy to perform the mathematical and computational operation with minimal time, irrespective of the large data. Our algorithm scheme preserves high-gradient regions that might exist in a given data set. We have tested our method with various data sets. The computational cost of our algorithm depends on the different approaches used. The initial triangulation can be done in $O(n \log n)$, the gradient approximation can be done in $O(n \log n)$. The individual refinement step has to check all the original data points lying in the involved triangles, so the complexity of each step is $O(n)$. How often the iteration step is executed depends on the error value given in the input. As a general rule, the authors have assumed that no more iteration should be done than they are original data sites. So the overall complexity is $O(n^2)$. We are currently investigating the detailed error analysis for the different sets of data sets at different scales.

7. ACKNOWLEDGEMENTS

Authors would like to thank various anonymous reviewers for their critical suggestions that improved the quality of the manuscript. LIDAR data was provided by Biswa Ranjan Patra.
